

# **Parallel Programming Principle and Practice**

---

## **Lecture 9 – Introduction to GPGPUs and CUDA Programming Model**

# Outline

---

- ❑ Introduction to GPGPUs and Cuda Programming Model
- ❑ The Cuda Thread Hierarchy / Memory Hierarchy
  - The Cuda Thread Hierarchy
  - The Cuda Memory Hierarchy
- ❑ Mapping Cuda to Nvidia GPUs

# Evolution of GPU Hardware

□ CPU architectures have used Moore's Law to increase

- The amount of on-chip cache
- The complexity and clock rate of processors
- Single-threaded performance of **legacy** workloads

□ GPU architectures have used Moore's Law to

- Increase the degree of on-chip parallelism and DRAM bandwidth
- Improve the flexibility and performance of graphics applications
- Accelerate general-purpose **Data-Parallel** workloads

# Cuda Programming Model Goals

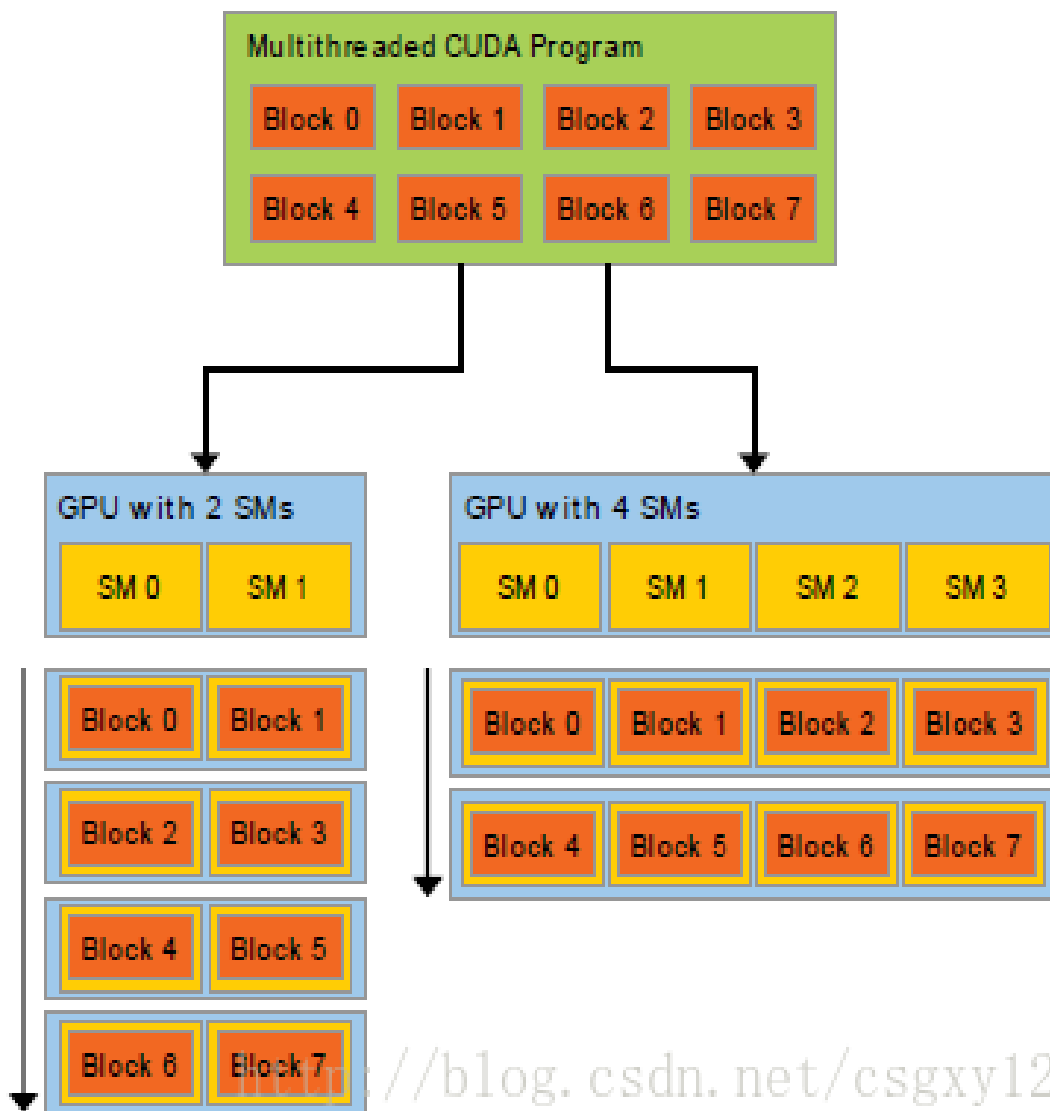

Provide an inherently scalable environment for Data-Parallel programming across a wide range of processors (Nvidia only makes GPUs, however)

Make SIMD hardware accessible to general-purpose programmers. Otherwise, large fractions of the available execution hardware are wasted!

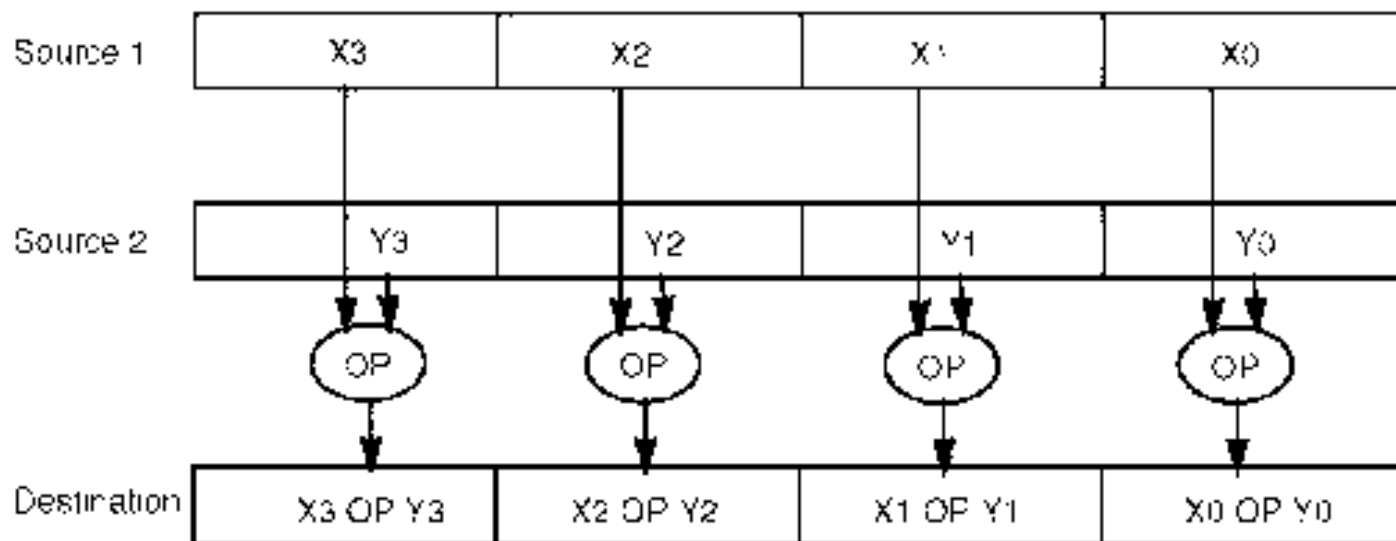

# Cuda Goals: Scalability

- ❑ Cuda expresses many independent blocks of computation that can be run in any order
- ❑ Much of the inherent scalability of the Cuda Programming model stems from batched execution of "Thread Blocks"
- ❑ Between GPUs of the same generation, many programs achieve linear speedup on GPUs with more "Cores"

# Cuda Goals: SIMD Programming

- ❑ Hardware architects love SIMD, since it permits a very space and energy-efficient implementation
- ❑ However, standard SIMD instructions on CPUs are inflexible, and difficult to use, difficult for a compiler to target
- ❑ The Cuda Thread abstraction will provide programmability at the cost of additional hardware

# Cuda C Language Extensions

- Code to run on the GPU is written in standard C/C++ syntax with a minimal set of extensions
  - Provide a MIMD Thread abstraction for SIMD execution
  - Enable specification of Cuda Thread Hierarchies
  - Synchronization and data-sharing within Thread Blocks
  - Library of intrinsic functions for GPU-specific functionality

```

__global__ void KernelFunc(...); // define a kernel callable from host
__device__ void DeviceFunc(...); // function callable only on the device
__device__ int GlobalVar; // variable in device memory
__shared__ int SharedVar; // in per-block shared memory
KernelFunc<<<500, 128>>>(...); // 500 blocks, 128 threads each
// Thread indexing and identification
dim3 threadIdx; dim3 blockIdx; dim3 blockDim;
__syncthreads(); // thread block synchronization intrinsic
sinf, powf, atanf, ceil, min, sqrtf, ... // <math.h> functionality
    
```

# Cuda Host Runtime Support

- Cuda is inherently a Heterogeneous programming model
  - Sequential code runs in a CPU “Host Thread”, and parallel “Device” code runs on the many cores of a GPU
  - The Host and the Device communicate via a PCI-Express link
  - The PCI-E link is slow (high latency, low bandwidth): it is desirable to minimize the amount of data transferred and the number of transfers
- Allocation/Deallocation of memory on the GPU
  - `CudaMalloc(void**, int), cudaFree(void*)`
- Memory transfers to/from the GPU
  - `cudaMemcpy(void*, void*, int, dir)`
  - Dir is `cudaMemcpy{Host, Device} To {Host, Device}`

# Hello World: Vector Addition

```
// Compute sum of length-N vectors:  $C = A + B$ 
void
vecAdd (float* a, float* b, float* c, int N) {
    for (int i = 0; i < N; i++)
        c[i] = a[i] + b[i];
}

int main () {
    int N = ... ;
    float *a, *b, *c;
    a = new float[N];
    // ... allocate other arrays, fill with data

    vecAdd (a, b, c, N);
}
```

# Hello World: Vector Addition

```
// Compute sum of length-N vectors:  $C = A + B$ 
void __global__
vecAdd (float* a, float* b, float* c, int N) {
    int i = blockIdx.x * blockDim.x + threadIdx.x;
    if (i < N) c[i] = a[i] + b[i];
}

int main () {
    int N = ... ;
    float *a, *b, *c;
    cudaMalloc (&a, sizeof(float) * N);
    // ... allocate other arrays, fill with data

    // Use thread blocks with 256 threads each
    vecAdd <<< (N+255)/256, 256 >>> (a, b, c, N);
}
```

# Cuda Software Environment

- ❑ nvcc compiler works much like icc or gcc: compiles C++ source code, generates binary executable
- ❑ Nvidia Cuda OS driver manages low-level interaction with device, provides API for C++ programs
- ❑ Nvidia Cuda SDK has many code samples demonstrating various Cuda functionalities
- ❑ Library support is continuously growing
  - CUBLAS for basic linear algebra
  - CUFFT for Fourier Transforms
  - CULapack (3<sup>rd</sup> party proprietary) linear solvers, eigen solvers, ...
- ❑ OS-Portable: Linux, Windows, Mac OS
- ❑ A lot of momentum in Industrial adoption of Cuda!

# Outline

- ❑ Introduction to GPGPUs and Cuda Programming Model
- ❑ The Cuda Thread Hierarchy / Memory Hierarchy
  - The Cuda Thread Hierarchy
  - The Cuda Memory Hierarchy
- ❑ Mapping Cuda to Nvidia GPUs

# Nvidia Cuda GPU Architecture

- ❑ The Cuda Programming Model is a set of data-parallel extensions to C, amenable to implementation on GPUs, CPUs, FPGAs, ...
- ❑ Cuda GPUs are a collection of “Streaming Multiprocessors”
  - Each SM is analogous to a core of a Multi-Core CPU
- ❑ Each SM is a collection of SIMD execution pipelines (Scalar Processors) that share control logic, register file, and L1 Cache

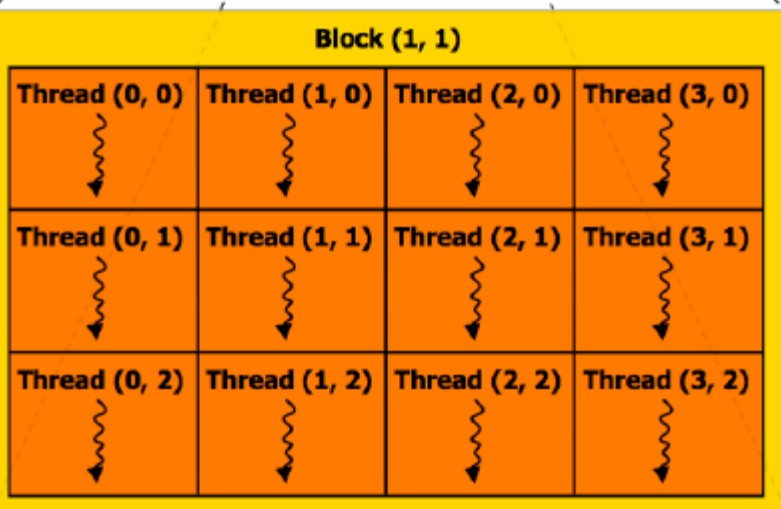

# Cuda Thread Hierarchy

- Parallelism in the Cuda Programming Model is expressed as a 4-level Hierarchy

- A **Stream** is a list of **Grids** that execute in-order. Fermi GPUs execute multiple Streams in parallel
- A **Grid** is a set of up to  $2^{32}$  **Thread Blocks** executing the same kernel
- A **Thread Block** is a set of up to 1024 [512 pre-Fermi] **Cuda Threads**
- Each **Cuda Thread** is an independent, lightweight, scalar execution context
- Groups of 32 threads form **Warps** that execute in lockstep SIMD

# What is a Cuda Thread?

- ❑ Logically, each Cuda Thread is its own very lightweight **independent MIMD execution context**
  - Has its own control flow and PC, register file, call stack, ...
  - Can access any GPU global memory address at any time
  - Identifiable uniquely within a grid by the five integers  
`threadIdx.{x,y,z}, blockIdx.{x,y}`
- ❑ **Very fine granularity:** do not expect any single thread to do a substantial fraction of an expensive computation
  - At full occupancy, each Thread has 21 32-bit registers
  - ... 1,536 Threads share a 64 KB L1 Cache / \_\_shared\_\_ mem
  - GPU has no operand bypassing networks: functional unit latencies must be hidden by multithreading or ILP (e.g. from loop unrolling)

# What is a Cuda Warp?

- ❑ The Logical SIMD Execution width of the Cuda processor
- ❑ A group of 32 Cuda Threads that execute simultaneously
  - Execution hardware is most efficiently utilized when all threads in a warp execute instructions from the same PC
  - If threads in a warp **diverge** (execute different PCs), then some execution pipelines go unused (predication)
  - If threads in a warp access aligned, contiguous blocks of DRAM, the accesses are **coalesced** into a single high-bandwidth access
  - Identifiable uniquely by dividing the Thread Index by 32
- ❑ Technically, warp size could change in future architectures
  - But many existing programs would break

# What is a Cuda Thread Block?

- A Thread Block is a **virtualized multi-threaded core**
  - Number of scalar threads, registers, and `_shared_` memory are configured dynamically at kernel-call time
  - Consists of a number (1-1024) of Cuda Threads, who all share the integer identifiers `blockIdx.{x,y}`
- ... executing a **data parallel task** of moderate granularity
  - The cacheable working-set should fit into the 128 kb (64kb, pre-Fermi) Register File and the 64KB (16KB) L1
  - Non-cacheable working set limited by GPU DRAM cache
  - All threads in a block share a (small) instruction cache
- Threads within a block synchronize via barrier-intrinsics and communicate via fast, on-chip shared memory

# What is a Cuda Grid?

- ❑ A set of Thread Blocks performing related computations
  - All threads in a single kernel call have the same entry point and function arguments, initially differing only in `blockIdx.{x,y}`
  - Thread blocks in a grid may execute any code they want, e.g. switch (`blockIdx.x`) {...} incurs no extra penalty
- ❑ Performance portability/scalability requires many blocks per grid: 1-8 blocks execute on each SM
- ❑ Thread blocks of a kernel call must be **parallel sub-tasks**
  - Program must be valid for ***any interleaving*** of block executions
  - The flexibility of the memory system technically allows Thread Blocks to communicate and synchronize in arbitrary ways ...
  - E.G. Shared Queue index: **OK!** Producer-Consumer: **RISKY!**

# What is a Cuda Stream?

- ❑ A sequence of commands (kernel calls, memory transfers) that execute in order
- ❑ For multiple kernel calls or memory transfers to execute concurrently, the application must specify multiple streams
  - Concurrent Kernel execution will only happen on Fermi
  - On pre-Fermi devices, Memory transfers will execute concurrently with Kernels

```

cudaStream_t s0, s1;
cudaStreamCreate (&s0);  cudaStreamCreate (&s1);

cudaMemcpyAsync (a0, cpu_a0, N0*sizeof(float),
                 cudaMemcpyHostToDevice, s0);
vecAdd <<<N0/256, 256, 0, s0>>> (a0, b0, c0, N0);

cudaMemcpyAsync (a1, cpu_a1, N1*sizeof(float),
                 cudaMemcpyHostToDevice, s1);
vecAdd <<<N1/256, 256, 0, s1>>> (a1, b1, c1, N1);
    
```

# Outline

---

- ❑ Introduction to GPGPUs and Cuda Programming Model
- ❑ The Cuda Thread Hierarchy / Memory Hierarchy
  - The Cuda Thread Hierarchy
  - The Cuda Memory Hierarchy
- ❑ Mapping Cuda to Nvidia GPUs

# Cuda Memory Hierarchy

- Each Cuda Thread has private access to a configurable number of registers
  - The 128 KB (64 KB) SM register file is partitioned among all resident threads
  - The Cuda program can trade degree of thread block concurrency for amount of per-thread state
  - Registers, stack spill into (cached, on Fermi) "local" DRAM if necessary

- Each Thread Block has private access to a configurable amount of scratchpad memory
  - The Fermi SM's 64 KB SRAM can be configured as 16 KB L1 cache + 48 KB scratchpad, or vice-versa\*
  - Pre-Fermi SM's have 16 KB scratchpad only
  - The available scratchpad space is partitioned among resident thread blocks, providing another concurrency-state tradeoff

\* selected via `cudaFuncSetCacheConfig()`

# Cuda Memory Hierarchy

- ❑ Thread blocks in all Grids share access to a large pool of “Global” memory, separate from the Host CPU’s memory
  - Global memory holds the application’s persistent state, while the thread-local and block-local memories are temporary
  - Global memory is much more expensive than on-chip memories:  $O(100)\times$  latency,  $O(1/50)\times$  (aggregate) bandwidth
- ❑ On Fermi, Global Memory is cached in a 768KB shared L2

# Cuda Memory Hierarchy

- ❑ There are other read-only components of the Memory Hierarchy that exist due to the Graphics heritage of Cuda
- ❑ The 64 KB Cuda **Constant Memory** resides in the same DRAM as global memory, but is accessed via special read-only 8 KB per-SM caches
- ❑ The Cuda **Texture Memory** also resides in DRAM and is accessed via small per-SM read-only caches, but also includes interpolation hardware
  - This hardware is crucial for graphics performance, but only occasionally is useful for general-purpose workloads
- ❑ The behaviors of these caches are highly optimized for their roles in graphics workloads

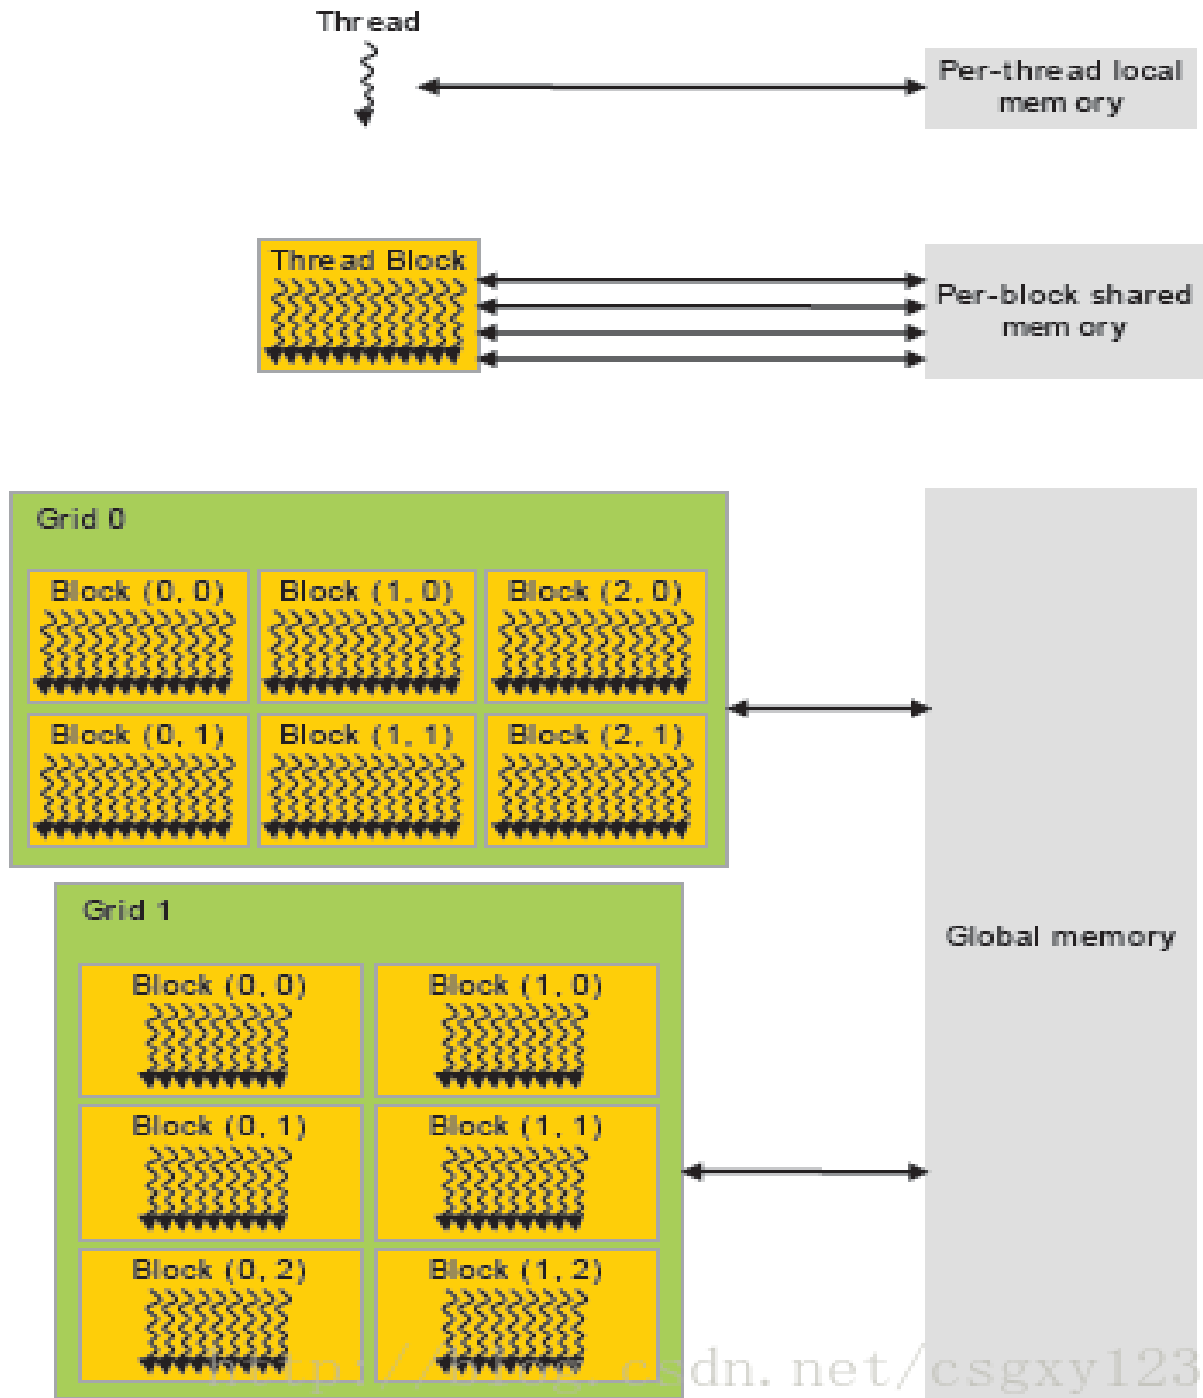

# Cuda Memory Hierarchy

- ❑ Each Cuda device in the system has its own Global memory, separate from the Host CPU memory
  - Allocated via `cudaMalloc()/cudaFree()` and friends
- ❑ Host  $\leftrightarrow$  Device memory transfers are via `cudaMemcpy()` over PCI-E, and are extremely expensive
  - microsecond latency, ~GB/s bandwidth
- ❑ Multiple Devices managed via multiple CPU threads

# Cuda Memory Hierarchy

# Thread-Block Synchronization

- Intra-block barrier instruction `__syncthreads()` for synchronizing accesses to `__shared__` and global memory
  - To guarantee correctness, must `__syncthreads()` before reading values written by other threads
  - All threads in a block must execute the same `__syncthreads()`, or the GPU will hang (not just the same number of barriers !)
- Additional intrinsics worth mentioning here:
  - `int __syncthreads_count(int), int __syncthreads_and(int), int __syncthreads_or(int)`

```
extern __shared__ float T[];
__device__ void
transpose (float* a, int lda){
    int i = threadIdx.x, j = threadIdx.y;
    T[i + lda*j] = a[i + lda*j];
    __syncthreads();
    a[i + lda*j] = T[j + lda*i];
}
```

# Using per-block shared memory

- The per-block shared memory / L1 cache is a crucial resource: without it, the performance of most Cuda programs would be hopelessly DRAM-bound
- Block-shared variables can be declared statically:

```
__shared__ int begin, end;
```

- Software-managed scratchpad is allocated statically:

```
__shared__ int scratch[128];
scratch[threadIdx.x] = ... ;
```

- ... or dynamically:

```
extern __shared__ int scratch[];
```

```
kernel_call <<< grid_dim, block_dim, scratch_size >>> ( ... );
```

- Most intra-block communication is via shared scratchpad:

```
scratch[threadIdx.x] = ...;
__syncthreads();
int left = scratch[threadIdx.x - 1];
```

# Using per-block shared memory

- ❑ Each SM has 64 KB of private memory, divided 16KB/48KB (or 48KB/16KB) into software-managed scratchpad and hardware-managed, non-coherent cache
  - Pre-Fermi, the SM memory is only 16 KB, and is usable only as software-managed scratchpad
- ❑ Unless data will be shared between Threads in a block, it should reside in registers
  - On Fermi, the 128 KB Register file is twice as large, and accessible at higher bandwidth and lower latency
  - Pre-Fermi, register file is 64 KB and equally fast as scratchpad

# Shared Memory Bank Conflicts

- ❑ Shared memory is **banked**: it consists of 32 (16, pre-Fermi) independently addressable 4-byte wide memories
  - Addresses interleave: **float \*p** points to a float in bank  $k$ ,  $p+1$  points to a float in bank  $(k+1) \bmod 32$
- ❑ Each bank can satisfy a single 4-byte access per cycle
  - A **bank conflict** occurs when two threads (in the same warp) try to access the same bank in a given cycle
  - The GPU hardware will execute the two accesses serially, and the warp's instruction will take an extra cycle to execute
- ❑ Bank conflicts are a second-order performance effect: even serialized accesses to on-chip shared memory is faster than accesses to off-chip DRAM

# Shared Memory Bank Conflicts

- Unit-Stride access is **conflict-free**
- Stride-2 access: thread  $n$  ***conflicts*** with thread  $16+n$
- Stride-3 access is **conflict-free**

# Shared Memory Bank Conflicts

- ☐ Three more cases of conflict-free access
- ☐ Permutations within a 32-  
float block are OK
- ☐ Multiple threads reading the **same memory address**
- ☐ **All threads** reading the same memory address is a ***broadcast***

# Atomic Memory Operations

- ❑ Cuda provides a set of instructions which execute atomically with respect to each other
  - Allow non-read-only access to variables shared between threads in shared or global memory
  - Substantially more expensive than standard load/stores
  - With voluntary consistency, can implement e.g. spin locks!

```
int atomicAdd (int*,int), float atomicAdd (float*, float), ...
...
int atomicMin (int*,int),
...
int atomicExch (int*,int), float atomicExch (float*,float), ...
int atomicCAS (int*, int compare, int val), ...
```

# Voluntary Memory Consistency

- ❑ By default, you cannot assume memory accesses are occur in the same order specified by the program
  - Although a thread's **own** accesses appear to that thread to occur in program order
- ❑ To enforce ordering, use **memory fence** instructions
  - `__threadfence_block()`: make all previous memory accesses visible to all other threads **within the thread block**
  - `__threadfence()`: make previous **global** memory accesses visible to all other threads **on the device**
- ❑ Frequently must also use the **volatile** type qualifier
  - Has same behavior as CPU C/C++: the compiler is forbidden from register-promoting values in volatile memory
  - Ensures that pointer dereferences produce load/store instructions
  - Declared as **volatile** float \*p; \*p must produce a memory ref.

# Mapping Cuda to Nvidia GPUs

- ❑ Cuda is designed to be "functionally forgiving"
  - Easy to get correct programs running
  - The more time you invest in optimizing your code, the more performance you will get
- ❑ Speedup is possible with a simple "Homogeneous SPMD" approach to writing Cuda programs
- ❑ Achieving performance requires an understanding of the hardware implementation of Cuda

- Warp  $\Leftrightarrow$  Logical SIMD width
- Thread Block  $\Leftrightarrow$  Streaming Multiprocessor
- Grid  $\Leftrightarrow$  Multiple SMs
- **Set of Streams  $\Leftrightarrow$  Whole GPU**

# Mapping Cuda to Nvidia GPUs

- ❑ Each level of the GPU's processor hierarchy is associated with a memory resource
  - Scalar Threads / Warps: Subset of register file
  - Thread Block / SM: shared memory (L1 Cache)
  - Multiple SMs / Whole GPU: Global DRAM
- ❑ Massive multi-threading is used to hide latencies: DRAM access, functional unit execution, PCI-E transfers
- ❑ A highly performing Cuda program must carefully trade resource usage for concurrency
  - More registers per thread  $\longleftrightarrow$  fewer threads
  - More shared memory per block  $\longleftrightarrow$  fewer blocks

# Memory, Memory, Memory

- ❑ A many core processor  $\equiv$  A device for turning a compute bound problem into a memory bound problem
  - **Memory concerns dominate performance tuning!**
- ❑ Memory is SIMD too! The memory systems of CPUs and GPUs alike require memory to be accessed in aligned blocks
  - **Sparse accesses waste bandwidth!**

2 words used, 8 words loaded:  
 $\frac{1}{4}$  effective bandwidth

- **Unaligned accesses waste bandwidth!**

4 words used, 8 words loaded:  
 $\frac{1}{2}$  effective bandwidth

# Cuda Summary

- ❑ The Cuda Programming Model provides a general approach to organizing Data Parallel programs for heterogeneous, hierarchical platforms
  - Currently, the only production-quality implementation is Cuda for C/C++ on Nvidia's GPUs
  - But Cuda notions of "Scalar Threads", "Warps", "Blocks", and "Grids" can be mapped to other platforms as well!
- ❑ A simple "Homogenous SPMD" approach to Cuda programming is useful, especially in early stages of implementation and debugging
  - But achieving high efficiency requires careful consideration of the mapping from computations to processors, data to memories, and data access patterns
